

# Runtimes

George Burgess IV / dyreshark  
VTLUUG Talk

# Credentials

- 💧 i.e. Me throwing names at you hoping you'll think I'm competent
- 💧 Also a chance for you to get used to my presentation style

# Worked at

- ◆ DataTactics
- ◆ Microsoft
  - ◆ OS Security
  - ◆ CLR
- ◆ [This summer] Google Research
  - ◆ For compilers/runtimes

# More bragging

- ◆ Worked with
  - ◆ C/C-with-classes-and-templates (6-7 years)
    - ◆ C++: 2-3 years
  - ◆ Python (5 years)
  - ◆ Java (6 years)
  - ◆ FP (Haskell, Clojure, ... fanboi for ~2 years)

# So what will this be about?

- ◆ Up to you
  - ◆ Three or four major sections
  - ◆ Spend more time where people are interested
  - ◆ JVM == main runtime
    - ◆ Can also talk about
      - ◆ CLR (Yup)
      - ◆ CPython (Ehh)
      - ◆ LLVM (Not-so-much)

# THERE ARE SO MANY RUNTIMES. WHYYYYY

- 💧 I know.
- 💧 Lots of the concepts transfer over. Trust me.

# Note:

- ◆ When I say “**the** JVM” or “**the** CLR”, I’m talking about Oracle’s HotSpot and Microsoft’s VM implementation.
- ◆ Mono and OpenJDK mostly similar to their big-company-developed counterparts
- ◆ I make no guarantees that what I say holds for all of them

# Section I: Basics

💧 Quick aside...

# First: What is a runtime?

💧 Audience?

# Runtime?

# Runtime

- ◆ Broadest sense is any sort of library that manages program state
  - ◆ Yes, even C has a “runtime”
  - ◆ ...But we don't care about that one.
    - ◆ We're going to deal with more complex ones!
    - ◆ YAY!

# So our focus will be on...

Runtimes that sit in languages at or higher-leveled than Java.

# EWWW JAVA

# ...So, what's in one of those?

- ◆ Primitive “runtimes” are bytecode interpreters.

```
if (program[i] == ADD_BYTE) {  
    stack.push(stack.pop() + stack.pop());  
} else if ...
```

# ...What else?

- ◆ They also generally have GCs (Garbage Collectors)

```
while (true) {  
    new Object();  
}
```

# ...And?

💧 Reflection!

```
def safeGetIter(q):
```

```
    if hasattr(q, '__iter__') and callable(q.__iter__):
```

```
        return q.__iter__()
```

# Und?

## ◆ Type-Safety

```
const int* arr = (const int*)"Hello, World!"; =>
```

CLASSCASTEXCEPTION AT

<<1 line of useful stack>>

<<100 lines of garbage>>

# There's more?

## 💧 Array bounds-checking

```
int a[5];
```

```
int b;
```

```
a[-1] = 9001;
```

```
assert(b == 9001);
```

# STOP WE GET IT

- 💧 Runtime libraries
- 💧 Code (re)loading
- 💧 Exceptions
- 💧 JIT (Just-In-Time) compiling
- 💧 Virtual dispatch everywhere
- 💧 Some level of protection over memory
- 💧 The lowest level language available is some sort of bytecode

# So that's generally what we're dealing with.

- ◆ I'm not going into all of this
  - ◆ George. What are you doing
    - ◆ This is a talk.
    - ◆ Not a 3-day long institute

# I'm needy

- ◆ I want to go into three specific parts:
  - ◆ Type safety
  - ◆ GC
  - ◆ JIT

**IF ONLY NEEDY  
AND DESPERATE  
WERE  
ATTRACTIVE  
QUALITIES.**

# !! WARNING !!

- ◆ Each of these (sans maybe type safety) is a massive topic of its own.
- ◆ I'll just go over them at a high level, dipping down when it gets fun.
  - ◆ Fun == “The computer does this so you can be lazy! YAY!”
- ◆ I've literally gone on for hours about GCs before.

# !!! DANGER !!!

- ◆ You need to pay attention to the first part to get how the second/third work. You can ignore me after the first part.

# !!!! CRITICAL !!!!

- 💧 This space intentionally left blank

# Let's go

- ◆ Type safety

# But before that

💧 Exercise time!

```
Object o = new Integer(1);
```

```
System.out.println(o.toString());
```

...Does it call `Object.toString` or `Integer.toString`?

# Integer!

- 💧 Yup. It calls `Integer.toString`.
- 💧 How does it know to do that?

# Layout of a class when you call 'new'

Class Header

Actual class data

Padding to make it align to 16 bytes  
(ASK ME ABOUT THIS THERE'S  
A COOL THING THE JVM DOES)

# ...Header?

- ◆ A magic number to identify the class
- ◆ Pointer or index into global array
  - ◆ Gets you to a struct that has all of the class info
    - ◆ Superclass, interfaces, method pointers, ...
      - ◆ LOOK HOW FAR I CAN NEST THESE
        - ◆ WOO HOO TABS

# So what does this mean?

- ◆ For any given object, you can “cheaply” look up just about anything about it

# What else does this mean?

- ◆ Every time you're not dealing with a concrete class with 0 children, you **have** to do virtual dispatch
  - ◆ i.e. instead of `call 0x1234`, you have to:
    - ◆ (Sometimes) load address of methods array
    - ◆ Load index in methods array
    - ◆ Call the result of that load

...So method calls are more expensive.

# Especially when it comes to interfaces!

💧 Wat. Why.

# Exercise!

💧 Say I had:

```
class Foo extends Object {  
    public String toString() { return "Foo"; }  
}
```

...What would the methods array look like?

# <Insert title here>

Object

Method Index	Address
0 (toString)	0x100
1 (wait)	0x200
2 (hashCode)	0x300
...	

Foo

Method Index	Address
0 (toString)	0x400
1 (wait)	0x200
2 (hashCode)	0x300
...	

# ...So

- ◆ That's exactly how it's done
- ◆ Calling toString is effectively
  - ◆ call `classPtr->methods[0];`
    - ◆ Index not guaranteed to be 0.
    - ◆ But it will be constant throughout the program's execution.

# We can't do this with interfaces though.

- ◆ Can implement 30 interfaces
  - ◆ How would we guarantee that IFoo.bar is **always** index N in an array?
    - ◆ ...Give each interface its own methods array

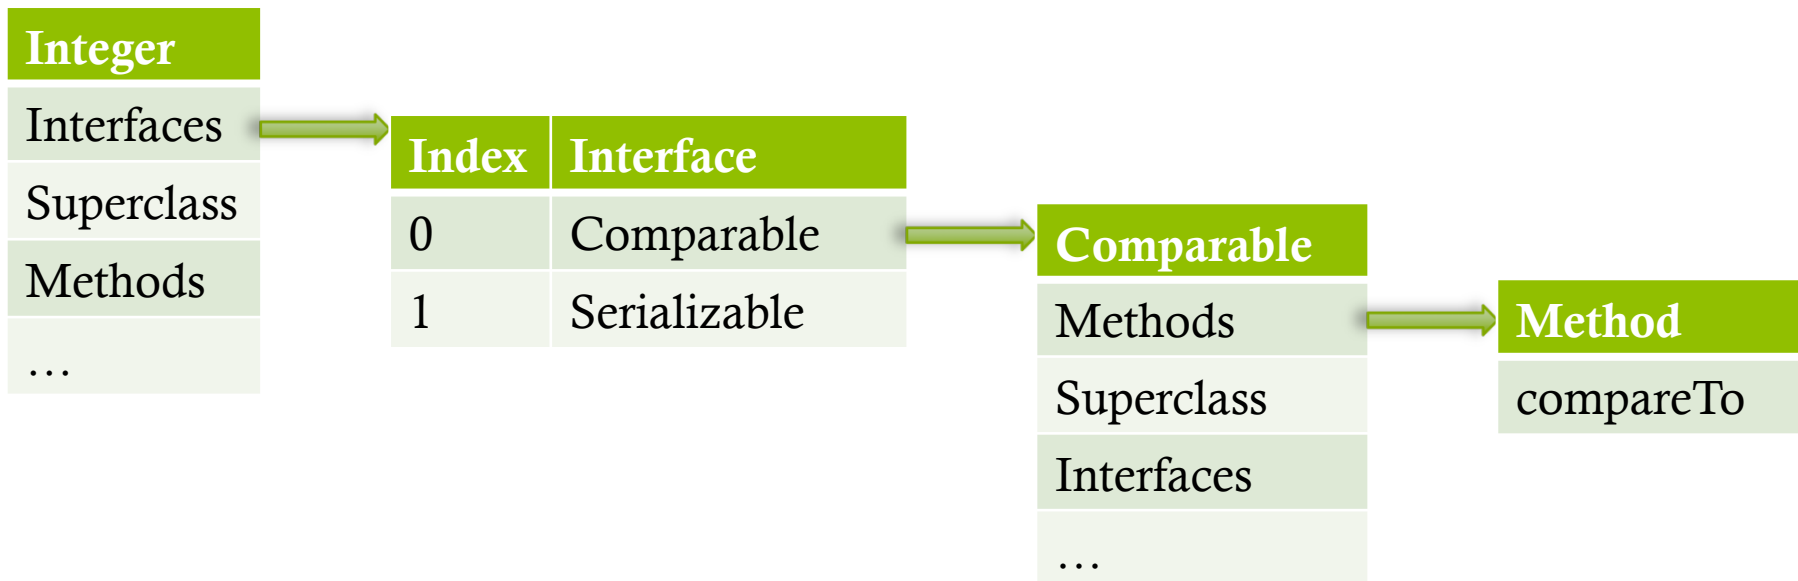

# ...So for interface dispatch

- ◆ We need to go through the interfaces array
  - ◆ Find the interface we're looking for (linear/logarithmic time WRT number of interfaces)
    - ◆ Constant matters more than Big-Oh\*
  - ◆ THEN load the methods from THAT interface
  - ◆ And go at our offset
  - ◆ And call that.

# Visualization

```
Comparable<Integer> i = new Integer(1);
```

```
i.compareTo(4);
```

# Yes. We just did multiple comparisons, multiple loads, etc...

- ◆ ALL TO CALL A SINGLE METHOD.
- ◆ WHY.
- ◆ THIS IS TERRIBLE.
- ◆ WHYYYYYYYYYYYYYYYYYYYYYYYYYYYYYY

# Enter: JITs

Questions? Comments? Stretch  
break?

Welcome to part 2. Where  
things get *really* fun.

# DISCLAIMER

- 💧 Very few people can guarantee when lots of optimizations will happen
  - 💧 I'm not one of them
- 💧 Profile then “optimize”.
  - 💧 But you can keep some of these in mind and mention them in code reviews
    - 💧 Makes you look smart and stuff

# What is a JIT?

- ◆ Just-In-Time compiler.
  - ◆ It turns bytecode (what Java/Python/C#/etc compile to) to machine code (x86, ARM, ...) at runtime
    - ◆ Why not just compile ahead of time (AOT)?
      - ◆ This is done in some cases
      - ◆ Has advantages
      - ◆ Has disadvantages
      - ◆ Interested? Ask. Else, we'll keep going.

# First off, how are they helpful?

💧 They turn

```
if (program[i] == ADD_BYTE) {  
    stack.push(stack.pop() + stack.pop());  
} else if ...
```

💧 Into

```
addl 4(%ebp), 8(%ebp)
```

# ...So?

- See JITTest.java

# Wao.

💧 Yes. Wao.

# How do they do this? Does compiling *really* help that much

- ◆ Short answer: no.
- ◆ Long answer: It's a combination of compiling and optimizing.

# Okay, okay, hold up. Why the “warmup” of 3,000 loops?

- 💧 This. Is. HOTSPOT!
  - 💧 Java won't JIT a method until it's been run a lot
    - 💧 Otherwise startup time suffers
      - 💧 JITing is EXPENSIVE.
        - 💧 ^ Moar? Ask about that

# Okay... So what does JITing do, in terms of optimizations?

- ◆ A LOT.

- ◆ Actually, most of the things GCC does

- ◆ But not everything

- ◆ But a lot more too

- ◆ What. But isn't C fast?

- ◆ Yes.

# So how does Java do MORE?

## It's so SLOW.

- ◆ 2-4x slower than C in “the normal case” (i.e. enterprise apps).
- ◆ The language speaks at a higher level, which means more assumptions can be made.\*
  - ◆ It **knows** you can only access inside of arrays
  - ◆ It **knows** you can't change class headers
  - ◆ It **knows** you can't do invalid casts
  - ◆ ...So it takes advantage of all of this.

# Examples of how JITTest could be optimized.

- ◆ Escape analysis – no need to heap alloc
- ◆ Constant prop.
- ◆ Virtual method call -> direct method call -> inlined
  - ◆ Okay, the virtual -> direct itself doesn't matter **so much**
    - ◆ Cache preloads
    - ◆ Branch prediction + speculative execution...
    - ◆ All make sure it's as fast as possible

# Let's go deeper...

- 💧 Because I sorta lied earlier.
- 💧 Comparable.

# What do we know?

- ◆ Comparable is an *interface*
  - ◆ From earlier, your reaction should be “EWWWW”
  - ◆ Let’s walk through a few things
    - ◆ Namely PICs
      - ◆ “MICs” on the CLR

# ...So virtual dispatch one more time.

- ◆ Marking a method as final means that the method cannot be overridden.
- ◆ Will this help performance?

# NO. The JVM is smarter than that.

- 💧 (At the cost of your arm, leg, and RAM)

# What.

- ◆ When optimizing methods, it only considers what's loaded
  - ◆ Is there only one concrete implementation of an abstract class?
    - ◆ Great! Do direct calls to that concrete implementation
    - ◆ Just add a note to recompile if another implementation is added
  - ◆ This expands to “it only considers what's overridden”.
    - ◆ There's one subclass of `ArrayList`, but it doesn't override `add()`?
      - ◆ Cool. No reason to virtual dispatch on `add()`.

Stop. Breathe. Stretch?  
Questions?

# Final stretch (ha): Garbage Collectors.

- ◆ There are multiple kinds, some overlapping:
  - ◆ Generational
  - ◆ Non-generational
  - ◆ Inaccurate
  - ◆ Accurate
  - ◆ Parallel
  - ◆ Serial
  - ◆ Refcounting\*
  - ◆ Mark+sweep

# The JVM

- ◆ It has 4+ standard GCs, and a few beta come in every now and then
- ◆ Generally, choose the best for your application.
- ◆ I'll not go over *all* of them, because some are still magic to me
  - ◆ Will still go over big points though

# JVM GCs (Pictured)

# The JVM's “standard” GC

- ◆ Has been G1 since JDK 7u4
- ◆ Before was concurrent mark+sweep (CMS)

# CMS is easier. Let's go with that.

- ◆ ...Because the basis for both is similar anyway.

# What's CMS

- ◆ Concurrent
- ◆ Mark+Sweep
- ◆ Generational

# Let's ignore concurrency, because YOLO.

- 💧 (It's actually really interesting, but it's added complexity we don't need. Oracle has lots of neat articles on it; I recommend you check it out!)
- 💧 Aside: MRI uses a generational M&S GC

# Mark+Sweep?

for allocation in all\_allocations:

    if has\_references(allocation):

        mark(allocation)

sweep\_away(a for a in all\_allocations if not marked(a))

# Generational?

- ◆ The heap is “sectioned off” into multiple parts. Parts we care about:
  - ◆ Permgen
  - ◆ Eden (“New gen”)
  - ◆ Survivor
  - ◆ Tenured (“Old gen”)

# Permgen

- .class file contents, along with a few other things. Rarely GCed, if at all. Things that are expected to live forever.

# New gen

- ◆ New allocations

# Old Gen

- 💧 OLD allocations
- 💧 Shock and awe

**HOLY SHIT!!!**

the easter bunny is the boogey man

Created on ebaumsworld.com

# Survivors

- ◆ ...Teenager allocations?

# How it looks

Courtesy of [http://www.oracle.com/technetwork/java/javase/gc-tuning-6-140523.html#generation\\_sizing](http://www.oracle.com/technetwork/java/javase/gc-tuning-6-140523.html#generation_sizing)

# ...Cool. Why?

- ◆ Because new != C/C++-style malloc. New looks like:
  - ◆ `void* result = eden_pointer;`
  - ◆ `eden_pointer += align16(sizeof(NewObject) + 4);`
  - ◆ `return result;`
    - ◆ 16-byte alloc alignment
    - ◆ Just a pointer bump.
    - ◆ Gets more interesting when parallel happens

# WHAT?!

- ◆ Yes. New is incredibly cheap.
  - ◆ This is because Eden GCs just walk Eden, finding all allocations that are still alive, and pop them in “survivor” territory.
  - ◆ After a survivor lives in survivor territory a few times, promoted to tenured/old gen
  - ◆ Old gen rarely collected

# Isn't this arbitrary?

- ◆ Nope. See this graph of knowledge

Courtesy of [http://www.oracle.com/technetwork/java/javase/gc-tuning-6-140523.html#generation\\_sizing](http://www.oracle.com/technetwork/java/javase/gc-tuning-6-140523.html#generation_sizing)

# What does it all mean?

- 💧 Most ( $> 90\%$ ) of allocations don't survive more than once.
- 💧 Those that do are  $\sim 50\%$  likely to not survive to old gen
- 💧 Those that do are likely to stay there for a long time

\*\* There are exceptions for large allocs/other things, but let's ignore those \*\*

# Takeaways

- ◆ GCs are expensive
  - ◆ But that makes `new` constant-time in the best+average cases
- ◆ If you have enough memory, you theoretically would never need to GC
- ◆ ...Theoretically.

# GCs done!

💧 WE MADE IT GUISE

# Other things I can ramble about if there's interest

- ◆ Array Bounds Checks – Condition “lifting”
- ◆ JIT – Arch-specific stuff
- ◆ JIT Styles
  - ◆ JVM
    - ◆ Advantages/Disadvantages
  - ◆ CLR
    - ◆ Advantages/Disadvantages

# Random commentary/AMA

- 💧 ...About runtimes
- 💧 Any questions at all
- 💧 About runtimes.

# Summary

- 💧 This is not going to get summarized in one slide.

# Summary [2]

- 💧 Runtimes can be really cool
- 💧 Runtimes can do a lot for you
- 💧 Runtimes can take a lot of memory

# Summary [3]

- ◆ The JVM is essentially the result of one brilliant idea:
  - ◆ “LET’S THROW EVERY THINKABLE OPTIMIZATION INTO ONE PIECE OF SOFTWARE AND SEE HOW IT PERFORMS”
- ◆ Has lots of GC algos
  - ◆ Most are generational
  - ◆ Lots are concurrent

# Summary [4]

- ◆ Profile, then optimize. Don't optimize, then profile
  - ◆ Remember the DistanceTo thing?
  - ◆ Optimized for you without dirtying up your  
AbstractFactoryAdapterFacadeVisitor pattern goodness!

# Summary [5]

💧 Thanks for your time! 😊
